<b>Example 2.0</b>	<p>The intercepts of a crystal plane with the <math>x</math>, <math>y</math> and <math>z</math>-axis defined by a set of unit vectors are at <math>2a_1</math>, <math>-3a_2</math> and <math>4a_3</math>, where <math>a_1</math>, <math>a_2</math> and <math>a_3</math> are the magnitudes of the unit vectors. Find the corresponding Miller indices of this and all other crystal planes parallel to this plane.</p>
Solution	<p>The Miller indices are obtained in the following three steps:</p> <ol style="list-style-type: none"> <li>1. Identify the intersections with the axis, namely 2, -3 and 4</li> <li>2. Calculate the inverse of each of those intercepts, resulting in <math>1/2</math>, <math>-1/3</math> and <math>1/4</math>.</li> <li>3. Find the smallest integers proportional to the inverse of the intercepts. Multiplying each fraction with the product of each of the intercepts (<math>24 = 2 \times 3 \times 4</math>) does result in integers, but not always the smallest integers. These are obtained in this case by multiplying each fraction by 12.</li> </ol> <p>The Miller indices of this plane and all parallel planes are therefore <math>(6\bar{4}3)</math>. Note that the negative indices are indicated with a bar above the integer for a more compact notation.</p>
